

Exponential Growth

An initial amount of A grows at rate r per year compounded n times per year. The amount after t years, denoted by $V(t)$ is given by

$$V(t) = A\left(1 + \frac{r}{n}\right)^{nt} \quad \text{Which is equivalent to}$$

$$V(t) = A \left[1 + \frac{1}{\left(\frac{n}{r}\right)} \right]^{\left(\frac{n}{r}\right)^{rt}}$$

We want to consider what happens to $V(t)$ as the number of compounding periods increases without bound. That is, becomes infinite.

Suppose we replace (n/r) with x .

$$V(t) = A \left\{ \left[1 + \frac{1}{x} \right]^x \right\}^{rt}$$

We can consider what happens to $V(t)$ as n becomes large by considering what happens as x becomes large. Complete the table below.

x	$\left[1 + \frac{1}{x}\right]^x$
10	
100	
1000	
10000	
100000	
1000000	

So, for very large values of x , $\left[1 + \frac{1}{x}\right]^x$ is about 2.7182.

Hence, for very large values of n ,

$$V(t) \approx A\{2.7182\}^{rt}$$

Actually, for arbitrarily large values of n , we have

$$(*) \quad V(t) \approx Ae^{rt}$$

$e \approx 2.7182$ and e is a number that cannot be expressed exactly as a decimal.

Continuous exponential growth (decay) is modeled by equation (*).
