

Primitive Data Types

integers

byte from -128 to 127 (8 bits = 1 byte)

short from -32,768 to 32,767 (16 bits = 2 bytes)

int from -2,147,483,648 to 2,147,483,647 (32 bits = 4 bytes)

long from -9,223,372,036,854,775,808 to
9,223,372,036,854,775,807 (64 bits = 8 bytes)

real numbers

float real numbers (with fractional components)

double more precise real numbers

other

boolean true or false values (only 1 bit)

char character (ASCII) (8 bits = 1 byte).

Main Memory (RAM)

- Is organized as a sequence of locations
- Each location can contain a sequence of bits, representing data or an instruction
- Locations are numbered with "addresses" from 0 to memory-size
(can be huge, even gigabytes)

0	1	2	3
10111101	10111110	01111101	00111110
4	5	6	7
10011111	11011111	00000000	00000000
8	9	10	11
00000000	00000000	00000000	00000000
12	13	14	15
00000000	00000000	00000000	00000000
16	17	18	19
00000000	00000000	00000000	00000000
20	21	22	23
00000000	00000000	00000000	00000000
24	25	26	27
00000000	00000000	00000000	00000000
28	29	30	31
00000000	00000000	00000000	00000000

Why use binary numbers?

- We could build computers that operate in base-10, but they would be expensive.
- What is easier than having a switch be ON or OFF?
- Electricity is used... that way: low current or high current.
- High voltages indicate 1 and low voltages indicate 0

Data Representation: Bits

The **bit** is the smallest unit of data; it is 1 or 0, that is, on or off

Base Ten Numbers

- In base 10, a *decimal integer* 587 means:

$$\begin{array}{r} 587 = 5 \times 10^2 + 8 \times 10^1 + 7 \times 10^0 \\ \begin{array}{l} \text{7} \times 10^0 = 7 \\ \text{8} \times 10^1 = 80 \\ \text{5} \times 10^2 = 500 \\ \hline 587 \end{array} \end{array}$$

Base Two

- Likewise, in base 2, a *binary integer* 101 means:

$$\begin{array}{r} 101 = 1 \times 2^2 + 0 \times 2^1 + 1 \times 2^0 \\ \begin{array}{l} \text{1} \times 2^0 = 1 \\ \text{0} \times 2^1 = 0 \\ \text{1} \times 2^2 = 4 \\ \hline 5 \end{array} \end{array}$$

Convert the binary (base two) number
110111 to decimal (base ten).

Answer = 55

$$\begin{array}{r}
 \begin{array}{cccccccc}
 0 & 0 & 1 & 1 & 0 & 1 & 1 & 1 \\
 \times 128 & \times 64 & \times 32 & \times 16 & \times 8 & \times 4 & \times 2 & \times 1 \\
 \hline
 + 0 & + 0 & + 32 & + 16 & + 0 & + 4 & + 2 & + 1 = 55
 \end{array}
 \end{array}$$

Convert the decimal (base ten) number
52 to binary (base two).

Answer = 00110100

$$\begin{array}{r}
 \begin{array}{ccccccc}
 52 & \times 32 & \times 16 & \times 8 & \times 4 & \times 2 & \times 1 \\
 \hline
 -32 & 1 & 1 & 0 & 1 & 0 & 0 \\
 \hline
 20 & & & & & & \\
 \hline
 -16 & & & & & & \\
 \hline
 4 & & & & & & \\
 \hline
 -4 & & & & & & \\
 \hline
 0 & & & & & &
 \end{array}
 \end{array}$$

How do we represent negative numbers Two's Complement

$$\begin{array}{r} 13 = \quad 0 \ 0 \ 0 \ 0 \ 1 \ 1 \ 0 \ 1 \\ \quad \quad 1 \ 1 \ 1 \ 1 \ 0 \ 0 \ 1 \ 0 \\ \quad \quad \hline \quad \quad \quad \quad \quad \quad \quad 1 \\ -13 = \quad 1 \ 1 \ 1 \ 1 \ 0 \ 0 \ 1 \ 1 \end{array} \quad \begin{array}{l} \textit{invert the digits} \\ \textit{add 1} \end{array}$$

Characters, marks, and more

Letters, numbers, line feeds, and non-printing characters

ASCII-8. Pronounced “ass-key” ASCII stands for American Standard Code for Information Interchange, has 256 different symbols-all Operating Systems fully understand ASCII.

UNICODE allows for up to 65,536 different characters. It is more complex and not implemented on many Operating Systems, but it is on Windows NT and Windows XP.

Different characters held in RAM

Why are these lists in alphabetical order?

ASCII, Cont.

- 32 is the ASCII code for a space.
- So 32 = 00100000 in binary, and when the computer gets that data, it causes a space to appear.
- Note: all the capital letters finish before the lower case letters appear
- B = 66
- b = 98
